Abstract: The Veporic–Gemeric contiguous zone is characterized by the presence of several major tectonic units exhibiting differing structural–metamorphic histories. Relying on the detailed structural, petrologic and geochronologic (EMPA dating of monazites) investigations, three main metamorphic stages have been distinguished. The first event (ca 360–355 Ma) is restricted to the Veporic basement and relates to the Variscan regional metamorphism and granitoid intrusions, the others two are Alpine in age. Ages around 145–140 Ma occur in the Meliatic HP Bôrka Nappe only and associate with its exhumation and thrust emplacement; while the mid-Cretaceous data (100–90 Ma) are found in all units and are likely connected with the main phase of the Western Carpathian nappe stacking and onset of the extension-related exhumation of the Veporic metamorphic dome.

Introduction

The contact zone of the Veporic and Gemeric basement-involved superunits in central Slovakia follows the Lubeník fault zone, which was the thrust plane of the latter over the former originally, later affected by significant transpressional and extensional reactivation. The deformation processes in this structurally complicated area resulted in a superposition and/or juxtaposition of several units that exhibit complex tectonic and metamorphic relationships. We present the structural, metamorphic and geochronologic data which constrain their tectonothermal evolution into three distinct stages.

Geological setting

Three superposed major Western Carpathian tectonic units in the investigated area between Čierna Lehota and Štítnik villages in central Slovakia occur (Fig. 1). The Veporic Superunit in the lowermost structural position includes the pre-Alpine crystalline basement and the post-Variscan Upper Paleozoic–Triassic sedimentary cover (Foederata Unit). The Veporic basement is composed of polymetamorphic (Variscan and Alpine) metasediments and scarce metavolcanics (Hladomorná dolina Complex; HDC) intruded by Variscan granitoids (Kráľova hoľa Complex; KHC — Klinec 1966, 1971). The HDC is discordantly overlain by clastic deposits of the Permian Rimava Formation as a part of the South Veporic sedimentary cover. In addition to the polyphase regional metamorphism, the HDC bears also superimposed contact metamorphic associations related to the hidden Upper Cretaceous granitic intrusion (Rochovce granite; Korikovsky et al. 1986; Poller et al. 2001; Kohút et al. 2013) which was drilled in its underlier (e.g., Klinec 1980).

Along the SW–NE trending Lubeník fault zone, which turns to the N–S direction in the investigated area, rocks of Veporic Rimava Fm. are juxtaposed to the Paleozoic complexes of the Gemeric Superunit. In the direct contact with the Veporic units, the Mississippian rocks of the Gemericum are represented by the Ochtiná Group overlain by the Pennsylvanian clastics of the Hámar Fm. (e.g., Vozárová 1996). The Ochtiná Unit is overthrust by the main Gemeric basement and cover thrust sheet represented by the Lower Paleozoic low-grade polymetamorphic volcano-sedimentary formations (Gelnica Group) and the Pennsylvanian–Permian cover clastics (Permian Gočaltovo Group in the area concerned).

The Gemeric rock complexes are overridden by the Meliatic Superunit. The Meliaticum is formed by the Bôrka Nappe (Mello et al. 1998) composed of the Permian to Jurassic HP/LT metamorphosed sedimentary and volcanic rocks, and very low-grade Jurassic syn-orogenic sedimentary formations with huge olistostrome bodies (Meliata Unit s.s.; Mock et al. 1998). Rocks of the Bôrka Nappe underwent Upper Jurassic blueschist-facies metamorphism and were subsequently affected by the Early Cretaceous greenschist-facies
retrogression (e.g., Plašienka et al. 2019 and references therein). Meliaticum is tightly imbricated and forms a combined accretionary complex with the overlying Turňa Unit represented by a system of partial nappes and duplexes consisting of low-grade Carboniferous to Triassic metasediments (Lačný et al. 2016). The structurally highest unit is the Silica Nappe, which overlies the Meliatic-Turnaic accretionary complex with a pronounced structural and metamorphic discordance (Reichwalder 1982).

The structural relationships of the Veporic–Gemeric–Turnaic–Meliatic thrust stack are described along two subparallel, NW–SE trending profile lines in the studied area (Fig. 1). The first profile A is located between the mountain ridges NW and SE of the Štítnik River valley. It crosses units of the Veporicum (KHC, HDC, Rimava Fm.), Gemericum (Ochtiná, Gelnica and Gočaltovo groups), Meliaticum (Bôrka Nappe), Turnaicum and Silicicum. The second profile (B in Fig. 1) follows the mountain ridge between valleys of the Štítnik and Muráň rivers and includes from NW to SE the Veporic (KHC, HDC, Rimava Formation), Gemeric (Ochtiná and Gočaltovo groups) and Meliatic units (Bôrka Nappe).

We investigated a number of samples, in part oriented, from all these units. Thin-sections were subjected to petrological study under the polarized microscope and electronic microanalyzer to obtain data about the lithology, metamorphism and microstructures. Several samples that contain metamorphic monazites were dated by the EMPA method providing ages that can be grouped into three main stages — one Variscan and two Alpine.

**Petrology, metamorphism and structures**

First representative of the Veporic basement is a skarnoid body occurring within the Variscan granitoids near...
The younger monazite generation (Mnz2) always occurs at the Devonian/Carboniferous boundary ages (359±4.2 Ma). Inclusions in garnets occur. EMPA dating of Mnz1 revealed dimensions from 10 µm to 30 µm and always as inclusions in garnets. The older monazites Mnz1 show a rounded habitus, most commonly in biotite or quartz. Mnz2 has a dendritic, strongly irregular habitus and is present in layers 30 µm to 100 µm thick along with older allanite. Mnz2 has the early Late Cretaceous age 92±7.2 Ma.

Two generations of monazites were identified in a mylonitic granite (Zlatná valley, NE of Slavošovce) located between the Variscan granitoids and Permian Rimava Fm. The older monazites (age around 355 Ma) are located in a massive fabric and they have dimensions from 100 µm to 50 µm. The younger monazites (ages around 100 Ma) are restricted to the Alpine foliation planes.

Numerous post-kinematic idiomorphic porphyroblasts of monazites (30–500 µm in size) were observed in the sericite-chlorite phyllites of the Bôrka Nappe (locality Honce, 10 km SE of Slavošovce). Monazites show a typical oscillation zonation which is reflected in their chemical composition. The EMPA dating of these monazites provided again two age groups: (1) 147±17 Ma and (2) 89±18 Ma.

We obtained other two distinct monazite age groups from the mylonitic granite and from garnet-biotite gneiss (NE of Chyžné village) located between the Variscan granitoid and HDC (profile line B in Fig. 1). The older monazites (age around 355 Ma) were obtained from the mylonitic granite, while younger monazite ages (around 88 Ma) were identified from the garnet-biotite gneiss. Analogous monazite age 88 Ma was provided on the contact of the metamorphosed cordierite–biotite gneiss from the HDC near the contact with the Permian Rimava Fm. (NE of Magura Hill).

Further on, two monazite ages were acquired from sericite-chlorite phyllites of the Bôrka Nappe (locality Hrádok, 5 km S of Slavošovce). These monazites are very fine-grained (below 30 µm, frequently below 15 µm). Dating provided two different age groups: older (1) monazites 139±13 Ma, and younger (2) monazites 97±5 Ma. Older monazites occur in the coarser-grained domains and younger monazites are always present as elongated grains aligned within the very fine-grained foliation domains. Microscopic observations indicate shearing along the foliation planes.

**Conclusions**

Three principal tectono-metamorphic events can be discerned based on our petrologic and structural investigations and monazite age data: (1) the oldest monazite ages from the skarnoid body and from the mylonitic
granites indicate the Variscan regional metamorphosis tacking from intrusion of granitoids into the Lower Paleozoic pelitic protolith of HDC; (2) the monazites age group around 145–140 Ma from sericite–chlorite phyllites of the Bôrka Nappe likely indicates exhumation related to thrusting of the Meliatic accretionary wedge over the lower-plate Veporic and Generic units, following subduction of the Meliata Ocean; (3) the youngest monazite age group from all analysed rocks records the Alpine overprint of the Veporic basement simultaneously with recrystallization of the Meliatic complexes during the main phase of the Western Carpathian nappe stacking and commencement of the extension-related exhumation of the Veporic metamorphic dome.
